This program is part of the software suite that accompanies the book

*The Elements of Computing Systems*

by Noam Nisan and Shimon Schocken

MIT Press

[www.idc.ac.il/tecs](http://www.idc.ac.il/tecs)

This software was developed by students at the Efi Arazi School of Computer Science at IDC

Chief Software Architect: Yaron Ukrainitz
Background

*The Elements of Computing Systems* evolves around the construction of a complete computer system, done in the framework of a 1- or 2-semester course.

In the first part of the book/course, we build the hardware platform of a simple yet powerful computer, called Hack. In the second part, we build the computer's software hierarchy, consisting of an assembler, a virtual machine, a simple Java-like language called Jack, a compiler for it, and a mini operating system, written in Jack.

The book/course is completely self-contained, requiring only programming as a pre-requisite.

The book's web site includes some 200 test programs, test scripts, and all the software tools necessary for doing all the projects.
The book’s software suite

(All the supplied tools are dual-platform: $\texttt{Xxx.bat}$ starts $\texttt{Xxx}$ in Windows, and $\texttt{Xxx.sh}$ starts it in Unix)

**Simulators**

($\texttt{HardwareSimulator}$, $\texttt{CPUEmulator}$, $\texttt{VMEmulator}$):

- Used to build hardware platforms and execute programs;
- Supplied by us.

**Translators** ($\texttt{Assembler}$, $\texttt{JackCompiler}$):

- Used to translate from high-level to low-level;
- Developed by the students, using the book’s specs; Executable solutions supplied by us.

**Other**

- $\texttt{Bin}$: simulators and translators software;
- $\texttt{builtIn}$: executable versions of all the logic gates and chips mentioned in the book;
- $\texttt{os}$: executable version of the Jack OS;
- $\texttt{TextComparer}$: a text comparison utility.
The Hack computer

The **hardware simulator** described in this tutorial can be used to build and test many different hardware platforms. In this book, we focus on one particular computer, called Hack.

Hack -- a 16-bit computer equipped with a screen and a keyboard -- resembles hand-held computers like game machines, PDA’s, and cellular telephones.

The first 5 chapters of the book specify the elementary gates, combinational chips, sequential chips, and hardware architecture of the Hack computer.

All these modules can be built and tested using the **hardware simulator** described in this tutorial.

That is how hardware engineers build chips for real: first, the hardware is designed, tested, and optimized on a software simulator. Only then, the resulting gate logic is committed to silicon.
I. Getting started

VII. The Hack Platform

Relevant reading (from “The Elements of Computing Systems”):
- Chapter 1: Boolean Logic
- Appendix A: Hardware Description Language
- Appendix B: Test Scripting Language
Part I: Getting Started
Chip Definition (.hdl file)

- Chip interface:
  - Name of the chip
  - Names of its input and output pins
  - Documentation of the intended chip operation

- Typically supplied by the chip architect; similar to an API, or a contract.
Chip Definition (.hdl file)

```haskell
/** Exclusive-or gate. out = a xor b */
CHIP Xor {
    IN a, b;
    OUT out;

    PARTS:
    Not(in=a, out=nota);
    Not(in=b, out=notb);
    And(a=a, b=notb, out=w1);
    And(a=nota, b=b, out=w2);
    Or(a=w1, b=w2, out=out);
}
```

- Any given chip can be implemented in several different ways. This particular implementation is based on: \( \text{Xor}(a,b) = \text{Or}(\text{And}(a,\text{Not}(b)), \text{And}(b,\text{Not}(a))) \)
- **Not, And, Or**: *Internal parts* (previously built chips), invoked by the HDL programmer
- **nota, notb, w1, w2**: *internal pins*, created and named by the HDL programmer; used to connect internal parts.
Loading a Chip

Navigate to a directory and select an .hdl file.
### Loading a Chip

- **Names and current values of the chip’s input pins:**
  - To change their values, enter the new values here.

- **Names and current values of the chip’s output pins:**
  - Calculated by the simulator; read-only.

- **Names and current values of the chip’s internal pins** (used to connect the chip’s parts, forming the chip’s logic):
  - Calculated by the simulator; read-only.

- **Read-only view of the loaded .hdl file:**
  - Defines the chip logic;
  - To edit it, use an external text editor.
Exploring the Chip Logic

1. Click the **PARTS** keyword

2. A table pops up, showing the chip’s internal parts (lower-level chips) and whether they are:
   - Primitive (“given”) or composite (user-defined)
   - Clocked (sequential) or unclocked (combinational)
Exploring the Chip Logic

1. Click any one of the chip **PARTS**

2. A table pops up, showing the input/output pins of the selected part (actually, its API), and their current values;

   A convenient debugging tool.
Interactive Chip Testing

1. **User**: changes the values of some input pins
2. **Simulator**: responds by:
   - Darkening the output and internal pins, to indicate that the displayed values are no longer valid
   - Enabling the *eval* (calculator-shaped) button.
3. **User**: Clicked the *eval* button
4. **Simulator**: re-calculate the values of the chip’s internal and output pins (i.e. applies the chip logic to the new input values)
5. To continue interactive testing, enter new values into the input pins and click the *eval* button.
Part II:
Test Scripts
Test Scripts

load Xor.hdl,
output-file Xor.out,
compare-to Xor.cmp,
output-list a%B3.1.3
   b%B3.1.3
   out%B3.1.3;
set a 0,
set b 0,
eval,
output;
set a 0,
set b 1,
eval,
output;
Etc.

Test scripts:
- Are used for specifying, automating and replicating chip testing
- Are supplied for every chip mentioned in the book (so you don’t have to write them)
- Can effect, batch-style, any operation that can be done interactively
- Are written in a simple language described in Appendix B of the book
- Can create an output file that records the results of the chip test
- If the script specifies a compare file, the simulator will compare the .out file to the .cmp file, line by line.

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>out</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
Loading a Script

To load a new script (.tst file), click this button;

Interactive loading of the chip itself (.hdl file) may not be necessary, since the test script typically contains a “load chip” command.
Script Controls

- **Executes the next simulation step**
- **Pauses the script execution**
- **Resets the script**
- **Multi-step execution, until a pause**
- **Controls the script execution speed**

**Script** = series of simulation steps, each ending with a semicolon.
Running a Script

Typical "init" code:
1. Loads a chip definition (.hdl) file
2. Initializes an output (.out) file
3. Specifies a compare (.cmp) file
4. Declares an output line format.
Running a Script

Comparison of the output lines to the lines of the .cmp file are reported.

Script execution ends

End of script - Comparison ended successfully
Viewing Output and Compare Files

Observation: This output file looks like a Xor truth table.

Conclusion: the chip logic (Xor.hdl) is apparently correct (but not necessarily efficient).
Part III:
Built-in Chips
Built-In Chips

General

- A built-in chip has an HDL interface and a Java implementation (e.g. here: `Mux16.class`)
- The name of the Java class is specified following the `BUILTIN` keyword
- Built-In implementations of all the chips that appear in the book are supplied in the `tools/buitIn` directory.

Built-in chips are used to:

- Implement primitive gates (in the computer built in this book: `Nand` and `DFF`)
- Implement chips that have peripheral side effects (like I/O devices)
- Implement chips that feature a GUI (for debugging)
- Provide the functionality of chips that the user did not implement for some reason
- Improve simulation speed and save memory (when used as parts in complex chips)
- Facilitate behavioral simulation of a chip before actually building it in HDL
- Built-in chips can be used either explicitly, or implicitly.
Explicit Use of Built-in Chips

The chip is loaded from the `tools/builtIn` directory (includes executable versions of all the chips mentioned in the book).

Standard interface.

Built-in implementation.
Implicit Use of Built-in Chips

When any HDL file is loaded, the simulator parses its definition. For each internal chip `Xxx(...)` mentioned in the PARTS section, the simulator looks for a `Xxx.hdl` file in the same directory (e.g. `Not.hdl`, `And.hdl`, and `Or.hdl` in this example).

If `Xxx.hdl` is found in the current directory (e.g. if it was also written by the user), the simulator uses its HDL logic in the evaluation of the overall chip.

If `Xxx.hdl` is not found in the current directory, the simulator attempts to invoke the file `tools/builtIn/Xxx.hdl` instead.

And since `tools/builtIn` includes executable versions of all the chips mentioned in the book, it is possible to build and test any of these chips before first building their lower-level parts.
Part IV:
Clocked Chips
(Sequential Logic)
Clocked (Sequential) Chips

- The implementation of clocked chips is based on *sequential logic*
- The operation of clocked chips is regulated by a master clock signal:

  ![Diagram of clock cycle](image)

  - In our jargon, a clock cycle = *tick*-phase (low), followed by a *tock*-phase (high)
  - During a *tick-tock*, the internal states of all the clocked chips are allowed to change, but their outputs are “latched”
  - At the beginning of the next *tick*, the outputs of all the clocked chips in the architecture commit to the new values
  - In a real computer, the clock is implemented by an oscillator; in simulators, clock cycles can be simulated either manually by the user, or repeatedly by a test script.
The D-Flip-Flop (DFF) Gate

**DFF:**
- A primitive memory gate that can “remember” a state over clock cycles
- Can serve as the basic building block of all the clocked chips in a computer.

```cpp
/** Data Flip-flop: */
* out(t) = in(t-1)
* where t is the time unit.
*/
CHIP DFF {
  IN in;
  OUT out;

  BUILTIN DFF;
  CLOCKED in, out;
}
```

Clocked chips
- Clocked chips include registers, RAM devices, counters, and the CPU
- The simulator knows that the loaded chip is clocked when one or more of its pins is declared “clocked”, or one or more of its parts (or sub-parts, recursively) is a clocked chip
- In the hardware platform built in the book, all the clocked chips are based, directly or indirectly, on (many instances of) built-in DFF gates.
Clocked (sequential) chips are clock-regulated. Therefore, the standard way to test a clocked chip is to set its input pins to some values (as with combinational chips), simulate the progression of the clock, and watch how the chip logic responds to the ticks and the tocks.

For example, consider the simulation of an 8-word random-access memory chip (RAM8). A built-in, clocked chip (RAM8) is loaded. Happens to be GUI-empowered, the simulator displays its GUI (More about GUI-empowered chips, soon)
Simulating Clocked Chips

1. User: enters some input values and clicks the clock icon once (tick)

A built-in, clocked chip (RAM8) is loaded

2. Simulator: changes the internal state of the chip, but note that the chip’s output pin is not yet effected.

3. User: clicks the clock icon again (tock)

4. Simulator: commits the chip’s output pin to the value of the chip’s internal state.
Simulating Clocked Chips Using a Test Script

Single-action tick-tock

Tick-tocks repeatedly and infinitely

Controls the script speed, and thus the simulated clock speed, and thus the overall chip execution speed

Default script: always loaded when the simulator starts running;
The logic of the default script simply runs the clock repeatedly;
Hence, executing the default script has the effect of causing the clock to go through an infinite train of tics and tocks.
This, in turn, causes all the clocked chip parts of the loaded chip to react to clock cycles, repeatedly.
Part V: GUI-Empowered chips
Built-in Chips with GUI Effects

1. A chip whose parts include built-in chips was loaded into the simulator (ignore the chip logic for now).

2. If the loaded chip or some of its parts have GUI side-effects, the simulator displays the GUI's here.

For each GUI-empowered built-in chip that appears in the definition of the loaded chip, the simulator does its best to put the chip GUI in this area.

The actual GUI's behaviors are then effected by the Java classes that implement the built-in chips.
The Logic of the GUIDemo Chip

// Demo of built-in chips with GUI effects
CHIP GUIDemo {
    IN in[16],load,address[15];
    OUT out[16];
    PARTS:
        RAM16K(in=in,load=load,address=address[0..13],out=null);
        Screen(in=in,load=load,address=address[0..12],out=null);
        Keyboard(out=null);
}

- **Effect**: When the simulator evaluates this chip, it displays the GUI side-effects of its built-in chip parts

- **Chip logic**: The only purpose of this demo chip is to force the simulator to show the GUI of some built-in chips. Other than that, the chip logic is meaningless: it simultaneously feeds the 16-bit data input (in) into the RAM16K and the Screen chips, and it does nothing with the keyboard.
GUIDemo Chip in Action

1. User enters:
   - $in = -1$ (=16 1's in binary)
   - $address = 5012$
   - $load = 1$

2. User: runs the clock

3. 16 black pixels are drawn beginning in row = 156, col = 320

Explanation: According to the specification of the computer architecture described in the book, the pixels of the physical screen are continuously refreshed from an 8K RAM-resident memory map implemented by the `Screen.hdl` chip. The exact mapping between this memory chip and the actual pixels is specified in Chapter 5. The refresh process is carried out by the simulator.

### Table: GUIDemo Chip in Action

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>$in$</td>
<td>-1</td>
</tr>
<tr>
<td>$load$</td>
<td>1</td>
</tr>
<tr>
<td>$address[15]$</td>
<td>5012</td>
</tr>
</tbody>
</table>

GUI Demos Chip in Action
Part VI: Debugging tools
System Variables

The simulator recognizes and maintains the following variables:

- **Time**: the number of time-units (clock-cycles) that elapsed since the script started running is stored in the variable `time`

- **Pins**: the values of all the input, output, and internal pins of the simulated chip are accessible as variables, using the names of the pins in the HDL code

- **GUI elements**: the values stored in the states of GUI-empowered built-in chips can be accessed via variables. For example, the value of register 3 of the `RAM8` chip can be accessed via `RAM8[3]`.

All these variables can be used in scripts and *breakpoints*, for debugging.
Breakpoints

The breakpoints logic:
- Breakpoint = (variable, value)
- When the specified variable in some breakpoint reaches its specified value, the script pauses and a message is displayed
- A powerful debugging tool.

1. Open the breakpoints panel
2. Previously-declared breakpoints
3. Add, delete, or update breakpoints

3. To update an existing breakpoint, double-click it
Scripts for Testing the Topmost Computer chip

- Scripts that test the CPU chip or the Computer chip described in the book usually start by loading a machine-language program (.asm or .hack file) into the ROM32K chip.

- The rest of the script typically uses various features like:
  - Output files
  - Loops
  - Breakpoints
  - Variables manipulation
  - tick, tock
  - Etc.

- All these features are described in Appendix B of the book (Test Scripting Language).

```plaintext
load Computer.hdl
ROM32K load Max.hack,
output-file ComputerMax.out,
compare-to ComputerMax.cmp,
output-list time%S1.4.1
    reset%B2.1.2
    ARegister[]%D1.7.1
    DRegister[]%D1.7.1
    PC[]%D0.4.0
    RAM16K[0]%D1.7.1
    RAM16K[1]%D1.7.1
    RAM16K[2]%D1.7.1;
breakpoint PC 10;
  // First run: compute max(3,5)
set RAM16K[0] 3,
set RAM16K[1] 5,
output;
repeat 14 {
    tick, tock, output;
}
  // Reset the PC (preparing for
  // second run)
set reset 1,
tick, tock, output;
  // Etc.
clear-breakpoints;
```
Visual Options

- **Program flow**: animates the flow of the currently loaded program
- **Program & data flow**: animates the flow of the current program and the data flow throughout the GUI elements displayed on the screen
- **No animation** (default): program and data flow are not animated.
- **Tip**: When running programs on the CPU or Computer chip, any animation effects slow down the simulation considerably.

Format of displayed pin values:
- **Decimal** (default)
- **Hexadecimal**
- **Binary**

- **Script**: displays the current test script
- **Output**: displays the generated output file
- **Compare**: displays the supplied comparison file
- **Screen**: displays the GUI effects of built-in chips, if any.
Part VII:
The Hack
Hardware Platform
Hack: a General-Purpose 16-bit Computer

Sample applications running on the Hack computer:

These programs (and many more) were written in the Jack programming language, running in the Jack OS environment over the Hack hardware platform. The hardware platform is built in chapters 1-5, and the software hierarchy in chapters 6-12.

</table>

Most of these chips are generic, meaning that they can be used in the construction of many different computers.

The Hack chip-set and hardware platform can be built using the hardware simulator, starting with primitive Nand.hdl and DFF.hdl gates and culminating in the Computer.hdl chip.

This construction is described in chapters 1,2,3,5 of the book, and carried out in the respective projects.
Aside: H.D. Thoreau about chips, bugs, and close observation:

I was surprised to find that the chips were covered with such combatants, that it was not a duellum, but a bellum, a war between two races of ants, the red always pitted against the black, and frequently two red ones to one black. The legions of these Myrmidons covered all the hills and vales in my wood-yard, and the ground was already strewn with the dead and dying, both red and black.

It was the only battle which I have ever witnessed, the only battlefield I ever trod while the battle was raging; internecine war; the red republicans on the one hand, and the black imperialists on the other. On every side they were engaged in deadly combat, yet without any noise that I could hear, and human soldiers never fought so resolutely.... The more you think of it, the less the difference. And certainly there is not the fight recorded in Concord history, at least, if in the history of America, that will bear a moment’s comparison with this, whether for the numbers engaged in it, or for the patriotism and heroism displayed.

From “Brute Neighbors,” Walden (1854).
